In this paper we calculate the transfer coefficients for evaporation and condensation of mixtures. We use the continuous profiles of various thermodynamic quantities through the interface, obtained in our previous works using the square gradient model. Furthermore we introduce the Gibbs surface and obtain the excess entropy production for a surface. Following the traditional non-equilibrium thermodynamic approach we introduce the surface transfer coefficients which we are able to determine from the continuous solution. The knowledge of these coefficients is important for many industrial applications which involve transport through a surface, such as for instance distillation. In our approach the values of the local resistivities in the liquid and the vapor phases are chosen on the basis of experimental values. In the interfacial region there are small peaks in these resistivities. Three amplitudes control the magnitude of these peaks. Possible values of these amplitudes are found by matching the diagonal transfer coefficients to values predicted by kinetic theory. Using these amplitudes we find that the value of the cross resistivities is 1-2 orders of magnitude higher than the one from kinetic theory. The results of both kinetic theory and molecular dynamics simulations support the existence of small peaks in the local resistivities in the interfacial region. The square gradient approach gives an independent way to determine the transfer coefficients for surfaces. The results indicate that kinetic theory underestimates the interfacial transfer coefficients in real fluids.

I. INTRODUCTION

In two earlier articles [1, 2] we developed the general approach for the square gradient description of an interface between two phases in non-equilibrium n -component mixtures. Using that approach it is possible to determine the continuous profiles of all variables through the interface during, for instance, evaporation and condensation. In this paper we will use these results to obtain the transfer coefficients for heat and mass transfer through the liquid vapor interface. The values of these transfer coefficients, or even their order of magnitude, is extremely important for industrial processes which involve evaporation and/or condensation of mixtures. Among these processes is, for instance, distillation, when one needs to separate components with different volatilities. As this involves evaporation and/or condensation repeatedly many times, it is very important to know the exact effect of the surface. Some values of the interfacial transfer coefficients may favor transport of one component, while the others may favor adsorption of a component at the surface. Of particular interest are the values of the cross coefficients, which contribute to reversible transport, and which are in most descriptions neglected [3].

A number of different methods have been used to obtain the surface transfer coefficients for one-component systems: experiments [4, 5, 6, 7], molecular dynamic simulations [8, 9, 10, 11, 12], kinetic theory [13, 14, 15, 16]. In a paper coauthored by one of us [17] the interfacial transfer coefficients obtained from the gradient theory for a one-component system were calculated and compared to the data in the above references. Even for one-component systems the database of interfacial transfer coefficients is poor and these data are pretty scattered. The situation is even worse for mixtures. There are only few experiments available for several systems [6, 7] at a very restrictive range of conditions, i.e. for instance, at infinite dilution. No molecular dynamic simulations are available yet. The only source of the values of interfacial coefficients is kinetic theory [15, 16]. This theory is most appropriate for short range potentials and low density gases. There is evidence from molecular dynamic simulations for longer range potentials [12] that the coupling transfer resistivities for liquid-vapor interfaces of real fluids are substantially larger than those predicted by kinetic theory.

In the first paper [1] we discussed the balance equations and the Gibbs relation for the square gradient model of mixtures. The Gibbs relation enabled us to derive the entropy production. It followed that if one uses as thermodynamic forces the gradient of the inverse temperature, $\nabla(1/T)$, minus the gradients of the chemical potential differences with the n th component divided by the temperature, $-\nabla[(\mu_j - \mu_n)/T]$, for $j = 1, \dots, n-1$, and minus the gradient of the velocity gradient divided by the temperature, $-(\nabla \mathbf{v})/T$, that the conjugate fluxes are the total heat flux, $\mathbf{J}_q$, the diffusion fluxes of the first $n-1$ components relative to the barycentric frame of reference, $\mathbf{J}_j$, and the viscous pressure tensor. Linear laws relating these forces and fluxes could then be given. Together with the balance equations it is then possible to calculate the profiles of all the variables. In the second paper [2] we gave details of the numerical

solution procedure for stationary states. We defined excess densities for an arbitrary dividing surface and verified that the non-equilibrium surface, as described by these excess densities following Gibbs, is in local equilibrium. Our work [1, 2] extended the analysis given by Johannessen et al. [18, 19].

Given the validity of local equilibrium for the description in terms of the Gibbs excess densities, it is possible to develop a description using non-equilibrium thermodynamics as explained in the monograph by Kjelstrup and Bedeaux [3]. This is much easier than the continuous description. As we will verify in this paper the expression for the excess entropy production of a surface has the general form

$$\hat{\sigma}_s = \sum_i J_i X_i \quad (\text{I.1})$$

In this expression J_i are the heat and mass fluxes through the surface and X_i are the jumps in the intensive variables across the interface. In non-equilibrium one uses the finite jumps of the temperature and chemical potentials across the surface, which lead to a non-zero entropy productions in the interfacial region. These jumps become the driving forces for the heat and mass transport through the interface. Following the traditional approach of non-equilibrium thermodynamics we then write the linear force-flux relations. These expressions use the interfacial resistivities or transfer coefficients which are the key interest of this paper.

Having the continuous profiles of thermodynamic quantities obtained from the non-equilibrium gradient model we are able to calculate these resistivities independently. This gives a way to determine the coefficients and therefore a possible source for comparison with future experiments and simulations.

In Sec. [II] we derive the expression for the local entropy production for stationary states in the continuous description. In Sec. [III] we discuss the properties of the excess quantities in three-dimensional space. We consider how the stationary state condition simplifies the non-equilibrium expressions. In Sec. [IV] we obtain the expression for the excess entropy production in an interfacial region. In Sec. [V] we give the force-flux relations and discuss the interfacial resistivity coefficients. We consider different sets of coefficients which are associated with different variables: gas- and liquid- side coefficients, as well as mass and molar coefficients. Any coefficient of one set is determined by the coefficients of the other set and equilibrium properties of pure bulk components. These sets are therefore equivalent. In Sec. [VI] we proceed to a particular two-component mixture and specify further details. In Sec. [VII] we discuss the different methods to obtain the resistivities from a non-equilibrium continuous solution. We give the results of our analysis in Sec. [VIII]. We analyze extensively different aspects of the problem and find the values of parameters, which make the interfacial resistivities obtained from the continuous solution of the gradient model to match kinetic theory. We give a discussion and concluding remarks in Sec. [IX].

II. LOCAL ENTROPY PRODUCTION.

A. Gibbs-Duhem equation.

Consider a two phase n -component mixture. Let T be the temperature field in this region, $\psi_i \equiv \mu_i - \mu_n$ be the chemical potential differences and p be the scalar pressure, which in case of a planar interface coincides with the parallel pressure $p_{\parallel}$. Furthermore, let u , s , v be the mass specific internal energy, entropy and volume respectively, $\rho \equiv 1/v$ be the overall mass density and $\xi_i \equiv \rho_i/\rho$ be the mass fraction of the i -th component. The explicit expressions for these quantities are given in [1]. It was found that the Gibbs equation for such a two phase system is given by:

$$T(\mathbf{r}, t) \frac{ds(\mathbf{r}, t)}{dt} = \frac{du(\mathbf{r}, t)}{dt} - \sum_{i=1}^{n-1} \psi_i(\mathbf{r}, t) \frac{d\xi_i(\mathbf{r}, t)}{dt} + p(\mathbf{r}, t) \frac{dv(\mathbf{r}, t)}{dt} - v(\mathbf{r}, t) \mathbf{v}_{\beta}(\mathbf{r}, t) \frac{\partial \gamma_{\alpha\beta}(\mathbf{r}, t)}{\partial x_{\alpha}} \quad (\text{II.1})$$

where $\mathbf{v}$ is the barycentric velocity, d/dt is a substantial time derivative and we use the summation convention over double Greek indices. $\gamma_{\alpha\beta}$ is the tension tensor, which is given by

$$\gamma_{\alpha\beta}(\mathbf{r}, t) = \kappa \frac{\partial \rho(\mathbf{r}, t)}{\partial x_{\alpha}} \frac{\partial \rho(\mathbf{r}, t)}{\partial x_{\beta}} + \sum_{i=1}^{n-1} \kappa_i \left(\frac{\partial \xi_i(\mathbf{r}, t)}{\partial x_{\alpha}} \frac{\partial \rho(\mathbf{r}, t)}{\partial x_{\beta}} + \frac{\partial \rho(\mathbf{r}, t)}{\partial x_{\alpha}} \frac{\partial \xi_i(\mathbf{r}, t)}{\partial x_{\beta}} \right) + \sum_{i,j=1}^{n-1} \kappa_{ij} \frac{\partial \xi_i(\mathbf{r}, t)}{\partial x_{\alpha}} \frac{\partial \xi_j(\mathbf{r}, t)}{\partial x_{\beta}} \quad (\text{II.2})$$

It is non-zero in particular in the interfacial region, where the gradient variables $\nabla \rho$ and $\nabla \xi_i$ are significant. All thermodynamic densities (except the entropy) have gradient contributions. For explicit expressions we refer to [1]. These densities are related by

$$u(\mathbf{r}, t) = \mu_n(\mathbf{r}, t) + \sum_{i=1}^{n-1} \psi_i(\mathbf{r}, t) \xi_i(\mathbf{r}, t) - p(\mathbf{r}, t) v(\mathbf{r}, t) + T(\mathbf{r}, t) s(\mathbf{r}, t) \quad (\text{II.3})$$

Substituting Eq. (II.3) into Eq. (II.1) we obtain

$$s \frac{dT}{dt} + \frac{d\mu_n}{dt} + \sum_{i=1}^{n-1} \xi_i \frac{d\psi_i}{dt} - v \frac{dp}{dt} - v v_\beta \frac{\partial \gamma_{\alpha\beta}}{\partial x_\alpha} = 0 \quad (\text{II.4})$$

This is the Gibbs-Duhem equation for a two-phase multi-component mixture. Note that since $\psi_i \equiv \mu_i - \mu_n$, we have

$$\frac{\partial \mu_n}{\partial x_\beta} + \sum_{i=1}^{n-1} \xi_i \frac{\partial \psi_i}{\partial x_\beta} = \sum_{i=1}^n \xi_i \frac{\partial \mu_i}{\partial x_\beta} \quad (\text{II.5})$$

which is the usual contribution to the Gibbs-Duhem equation associated with the chemical potentials.

For a stationary state the derivative $\partial/\partial t = 0$ and Eq. (II.4) takes the following form

$$v_\beta \left(s \frac{\partial T}{\partial x_\beta} + \frac{\partial \mu_n}{\partial x_\beta} + \sum_{i=1}^{n-1} \xi_i \frac{\partial \psi_i}{\partial x_\beta} - v \frac{\partial \sigma_{\alpha\beta}}{\partial x_\alpha} \right) = 0 \quad (\text{II.6})$$

where $\sigma_{\alpha\beta} = p \delta_{\alpha\beta} + \gamma_{\alpha\beta}$ is the thermodynamic pressure tensor.

B. Entropy balance.

The entropy balance equation is

$$\rho \frac{ds}{dt} = -\nabla \cdot \mathbf{J}_s + \sigma_s \quad (\text{II.7})$$

with the entropy flux $\mathbf{J}_s \equiv \mathbf{J}_{s,tot} - \rho s \mathbf{v}$ and the entropy production σ_s . These were found to be

$$\mathbf{J}_s = \frac{1}{T} \left(\mathbf{J}_q - \sum_{i=1}^{n-1} \psi_i \mathbf{J}_i \right) \quad (\text{II.8a})$$

$$\sigma_s = \mathbf{J}_q \cdot \nabla \frac{1}{T} - \sum_{i=1}^{n-1} \mathbf{J}_i \cdot \nabla \frac{\psi_i}{T} - \pi_{\alpha\beta} \frac{1}{T} \frac{\partial v_\alpha}{\partial x_\beta} \quad (\text{II.8b})$$

where $\mathbf{J}_q$ and $\mathbf{J}_i$ are the heat and diffusion fluxes

$$\begin{aligned} \mathbf{J}_q &\equiv \mathbf{J}_e - \rho \mathbf{v} e - p \mathbf{v} - \pi \cdot \mathbf{v} = \mathbf{J}_e - \mathbf{J}_m (e + p v) - \pi \cdot \mathbf{v} \\ \mathbf{J}_i &\equiv \rho_i (\mathbf{v}_i - \mathbf{v}) = \mathbf{J}_{\xi_i} - \xi_i \mathbf{J}_m \end{aligned} \quad (\text{II.9})$$

where $\pi \equiv \pi_{\alpha\beta}$ is the viscous pressure tensor. The energy flux $\mathbf{J}_e$ and the mass fluxes $\mathbf{J}_{\xi_i} \equiv \rho_i \mathbf{v}_i$ and $\mathbf{J}_m \equiv \rho \mathbf{v}$ are convenient quantities since in stationary states

$$\nabla \cdot \mathbf{J}_e = 0, \quad \nabla \cdot \mathbf{J}_{\xi_i} = 0, \quad \nabla \cdot \mathbf{J}_m = 0 \quad (\text{II.10})$$

Furthermore, it follows from Eq. (II.7) that in stationary state

$$\sigma_s = \nabla \cdot \mathbf{J}_{s,tot} = \nabla \cdot \mathbf{J}_s + \rho \mathbf{v} \cdot \nabla s = \nabla \cdot (\mathbf{J}_{s,tot} + \rho s \mathbf{v}) \quad (\text{II.11})$$

Using (II.6) and the conservation laws under stationary conditions, it is possible to show that

$$\sigma_s = \mathbf{J}_e \cdot \nabla \frac{1}{T} - \sum_{i=1}^n \mathbf{J}_{\xi_i} \cdot \nabla \frac{\mu_i}{T} - \mathbf{J}_m \cdot \nabla \frac{v^2/2 - \mathbf{g} \cdot \mathbf{r}}{T} - \frac{\partial}{\partial x_\alpha} \frac{\pi_{\alpha\beta} v_\beta}{T} \quad (\text{II.12})$$

The expression for the entropy production, used in Eq. (II.12) contains dependent fluxes $\mathbf{J}_{\xi_i}$ and $\mathbf{J}_m$ and thus force-flux relations cannot be obtained from it directly.

III. EXCESSES IN THREE-DIMENSIONAL SPACE.

A. Definition of an excess.

The definition of an excess requires the normal direction $\mathbf{n}$ to be defined in the interfacial region. The surface may be curved and we may introduce curvilinear orthogonal coordinates (x_1, x_2, x_3) with $\mathbf{r}_\perp \equiv x_1$ being the normal coordinate and $\mathbf{r}_\parallel \equiv (x_2, x_3)$ being the tangential coordinates.

Let $x^{g,s}$ and $x^{\ell,s}$ be the boundaries of the interfacial region at the gas and liquid side respectively. Let ϕ be a function defined in the surface region. Furthermore let ϕ^b , where superscript b stands either for ℓ or for g , be the function ϕ extrapolated from the bulk to the surface region. The extrapolation is done using the description in homogeneous phases which does not contain gradient contributions. Outside of the interfacial region ϕ^b and ϕ are identical but inside the surface, ϕ^b in general differs from ϕ . We note the following identity for the extrapolated functions

$$\phi^b(x^{b,s}, \mathbf{r}_\parallel) = \phi(x^{b,s}, \mathbf{r}_\parallel) \quad (\text{III.1})$$

Furthermore, for any function F

$$F^b(\dots, \phi, \dots) = F(\dots, \phi^b, \dots) \quad (\text{III.2})$$

in the interfacial region, since for the bulk functions outside the interfacial region it is identity. We note however, that even though Eq. (III.1) and Eq. (III.2) are exact, any numerical procedure will break these equalities. This happens because the extrapolation procedure usually involves polynomials in order to fit an actual curve, which introduces a non-zero error in the extrapolated curve.

We then can define the excess $\widehat{\phi}(x^s, \mathbf{r}_\parallel)$ of a density $\phi(\mathbf{r})$ per unit of volume in the 3-dimensional space as¹ [20]

$$\widehat{\phi}(x^s, \mathbf{r}_\parallel) \equiv \frac{1}{h_2^s h_3^s} \int_{x^{g,s}}^{x^{\ell,s}} dx_1 h_1 h_2 h_3 \phi^{ex}(\mathbf{r}; x^s) \quad (\text{III.3})$$

where

$$\phi^{ex}(\mathbf{r}; x^s) \equiv \phi(\mathbf{r}) - \phi^g(\mathbf{r}) \Theta(x^s - x_1) - \phi^\ell(\mathbf{r}) \Theta(x_1 - x^s) \quad (\text{III.4})$$

Furthermore, $h_i \equiv h_i(x_1, \mathbf{r}_\parallel)$ are Lamé coefficients for curvilinear coordinates and $h_i^s \equiv h_i(x^s, \mathbf{r}_\parallel)$. Given that $\phi(\mathbf{r})$ is a density per unit of volume, excess $\widehat{\phi}(x^s, \mathbf{r}_\parallel)$ is a density per unit of surface. The excess depends on the position of the dividing surface x^s , which is the coordinate of the surface in the normal direction, and the position $\mathbf{r}_\parallel$ along the surface.

B. Stationary state of a surface.

Consider the entropy production given in Eq. (II.12). All the terms but last one have the form $\mathbf{J} \cdot \nabla \phi$, where according to Eq. (II.10) $\nabla \cdot \mathbf{J} = 0$ and ϕ is some scalar function. Thus, $\mathbf{J} \cdot \nabla \phi = \nabla \cdot (\mathbf{J} \phi)$. We show in Appendix [A 2] that

$$\widehat{\mathbf{J} \cdot \nabla \phi} = (J_\perp \phi)^\ell - (J_\perp \phi)^g + \widehat{\nabla_\parallel \cdot (\mathbf{J}_\parallel \phi)} \quad (\text{III.5})$$

where all the functions on the right hand side are evaluated at $\mathbf{r}^s$.

For each flux in Eq. (II.10) we can write $\nabla_\perp J_\perp + \nabla_\parallel \cdot \mathbf{J}_\parallel = 0$. This gives an approximate relation for the order of magnitude

$$\frac{|\Delta_\perp J_\perp|}{\Delta x_\perp} \simeq \frac{|\Delta_\parallel J_\parallel|}{\Delta x_\parallel} \quad (\text{III.6})$$

¹ In the literature one also uses an alternative definition, which we show to be wrong in the Appendix [A 1].

As was discussed in [1], the interfacial region breaks the 3-dimensional isotropy of the system. In addition to a typical macroscopic size of the problem ℓ , there exists the microscopic size δ , the surface width, which is of the order of few nanometers. There are quantities which change drastically on the distances of the order δ in the direction perpendicular to the surface. However, the significant change of any quantity along the surface may happen only on a length scale ℓ , which is of the order of either radii of curvature or the system size. Because of this property of a surface, we may not expect the change of the parallel component of a flux on a macroscopic scale along the surface to be much larger than the change of the perpendicular component of that flux on a microscopic scale through the surface. For the fluxes for which changes $|\Delta_{\perp} J_{\perp}|$ and $|\Delta_{\parallel} J_{\parallel}|$ are of the same order of magnitude, Eq. (III.6) takes the form $\Delta J/\delta \approx \Delta J/\ell$, which can hold only if $\Delta J = 0$, since $\delta \ll \ell$. This means that both $\Delta_{\perp} J_{\perp} = 0$ and $\Delta_{\parallel} J_{\parallel} = 0$. If $|\Delta_{\perp} J_{\perp}| \gg |\Delta_{\parallel} J_{\parallel}|$ this statement becomes even stronger. We then may require that for a thin surface²

$$\nabla_{\perp} J_{\perp}(\mathbf{r}) = 0 \quad (\text{III.7a})$$

$$\nabla_{\parallel} \cdot \mathbf{J}_{\parallel}(\mathbf{r}) = 0 \quad (\text{III.7b})$$

Thus, a stationary state condition $\nabla \cdot \mathbf{J} = 0$ has a form of Eq. (III.7) in an interfacial region. The extrapolated fluxes $\mathbf{J}^b$ satisfy the same equation

$$\nabla_{\perp} J_{\perp}^b(\mathbf{r}) = 0 \quad (\text{III.8a})$$

$$\nabla_{\parallel} \cdot \mathbf{J}_{\parallel}^b(\mathbf{r}) = 0 \quad (\text{III.8b})$$

since the extrapolated flux fields also satisfy $\nabla \cdot \mathbf{J}^b = 0$.

Both Eq. (III.7a) and Eq. (III.8a) are first order ordinary differential equations which depend on a constant. These constants must be the same, since according to Eq. (III.1) $J_{\perp}^b(\mathbf{r}^{b,s}) = J_{\perp}(\mathbf{r}^{b,s})$ at boundary points. It means that $J_{\perp}^b$ and $J_{\perp}$ are the same functions³:

$$J_{\perp}^g(\mathbf{r}) = J_{\perp}^{\ell}(\mathbf{r}) = J_{\perp}(\mathbf{r}) \quad (\text{III.9})$$

Consider the last term in Eq. (III.5). Since parallel divergences of both $\mathbf{J}_{\parallel}$ and $\mathbf{J}_{\parallel}^b$ are zero

$$\widehat{\nabla_{\parallel} \cdot (\mathbf{J}_{\parallel} \phi)} = \widehat{\mathbf{J}_{\parallel} \cdot \nabla_{\parallel} \phi} \quad (\text{III.10})$$

where we used that $\nabla_{\parallel} \Theta(x_1) = 0$.

Substituting Eq. (III.9) and Eq. (III.10) into Eq. (III.5) we obtain

$$\widehat{\mathbf{J} \cdot \nabla \phi} = J_{\perp}(\phi^{\ell} - \phi^g) + \widehat{\mathbf{J}_{\parallel} \cdot \nabla_{\parallel} \phi} \quad (\text{III.11})$$

where all the functions on the right hand side are evaluated at $\mathbf{r}^s$.

IV. EXCESS ENTROPY PRODUCTION.

Applying Eq. (III.11) to each term in Eq. (II.12) for the entropy production we obtain the general form of the excess entropy production for a surface in stationary state

$$\begin{aligned} \widehat{\sigma}_s &= J_{s,tot\perp}^{\ell} - J_{s,tot\perp}^g + \widehat{\nabla_{\parallel} \cdot \mathbf{J}_{s,tot\parallel}} = \\ &= J_{e,\perp} \left(\frac{1}{T^{\ell}} - \frac{1}{T^g} \right) - \sum_{i=1}^n J_{\xi_i,\perp} \left(\frac{\tilde{\mu}_i^{\ell}}{T^{\ell}} - \frac{\tilde{\mu}_i^g}{T^g} \right) - \left(\frac{\pi_{\perp\beta}^{\ell} v_{\beta}^{\ell}}{T^{\ell}} - \frac{\pi_{\perp\beta}^g v_{\beta}^g}{T^g} \right) \\ &\quad + \left(\widehat{\mathbf{J}_{e,\parallel} \cdot \nabla_{\parallel} \frac{1}{T}} \right) - \sum_{i=1}^n \left(\widehat{\mathbf{J}_{\xi_i,\parallel} \cdot \nabla_{\parallel} \frac{\tilde{\mu}_i}{T}} \right) - \left(\widehat{\nabla_{\parallel} \cdot \frac{\pi_{\parallel\beta} v_{\beta}}{T}} \right) \end{aligned} \quad (\text{IV.1})$$

² For the special case of a system with planar surface in cartesian coordinated with all the fluxes directed perpendicular to the surface, which is the case studied in this paper, these equations follow straightforwardly.

³ Note that Eq. (III.9) does not lead to the relation $J_{\perp}(x^{g,s}, \mathbf{r}_{\parallel}) = J_{\perp}(x^{\ell,s}, \mathbf{r}_{\parallel})$. Eq. (III.9) is the relation between values of different functions at the same point but not the relation between values of the same function at different points. However, it follows from Eq. (III.7a) that in curvilinear coordinates $\partial(h_2 h_3 J_{\perp})/(\partial x_{\perp}) = 0$ and therefore $h_2 h_3 J_{\perp} = \text{const}$ but not $J_{\perp} = \text{const}$.

where $\tilde{\mu}_i \equiv \mu_i + v^2/2 - \mathbf{g} \cdot \mathbf{r}^s$.

The next step of the analysis is to provide constitutive relations in order to relate thermodynamic forces X_k to thermodynamic fluxes J_k for the whole surface. This requires that the excess entropy production has a form $\hat{\sigma}_s = \sum J_k X_k$. However, as one can see from Eq. (IV.1), the terms related to fluxes along the surface do not have this form. One has to make further assumptions on the nature of these terms to write them in this form. As our work is focused on transport into and through the surface we will not consider non-equilibrium perturbations which are applied along the surface. This guarantees that all the terms along the surface are equal to zero. The only nonzero component of any flux $\mathbf{J}$ is therefore $J_\perp$, which we will denote simply as J . We will furthermore restrict ourself to non-viscous fluids. The expression for the excess entropy production simplifies to the following

$$\hat{\sigma}_s = J_e \left(\frac{1}{T^\ell} - \frac{1}{T^g} \right) - \sum_{i=1}^n J_{\xi_i} \left(\frac{\tilde{\mu}_i^\ell}{T^\ell} - \frac{\tilde{\mu}_i^g}{T^g} \right) \quad (\text{IV.2})$$

It is convenient to write the excess entropy production in terms of the measurable heat flux $\mathbf{J}'_q$, rather than the total energy flux $\mathbf{J}_e$, which is defined as

$$\mathbf{J}'_q \equiv \mathbf{J}_q - \sum_{i=1}^n h_i \mathbf{J}_i = \mathbf{J}_e - \sum_{i=1}^n \tilde{h}_i \mathbf{J}_{\xi_i} \quad (\text{IV.3})$$

where we used Eq. (II.9) and $\tilde{h}_i \equiv h_i + v^2/2 - \mathbf{g} \cdot \mathbf{r}^s = \tilde{\mu}_i + T s_i$, where s_i is the partial entropy and h_i is the partial enthalpy. While Eq. (III.9) is valid for $\mathbf{J}_e$ and $\mathbf{J}_{\xi_i}$ it is not valid for $\mathbf{J}'_q$: the difference between the measurable heat fluxes extrapolated from the gas and the liquid side is

$$J'^{g}_q - J'^{\ell}_q = \sum_{i=1}^n J_{\xi_i} (\tilde{h}_i^\ell - \tilde{h}_i^g) \quad (\text{IV.4})$$

In terms of measurable heat fluxes the expression for the entropy production becomes

$$\hat{\sigma}_s = J'^{g}_q \left(\frac{1}{T^\ell} - \frac{1}{T^g} \right) - \sum_{i=1}^n J_{\xi_i} \frac{1}{T^\ell} (\tilde{\mu}_i^\ell - \tilde{\mu}_i^g + s_i^g (T^\ell - T^g)) \quad (\text{IV.5a})$$

$$\hat{\sigma}_s = J'^{\ell}_q \left(\frac{1}{T^\ell} - \frac{1}{T^g} \right) - \sum_{i=1}^n J_{\xi_i} \frac{1}{T^g} (\tilde{\mu}_i^\ell - \tilde{\mu}_i^g + s_i^\ell (T^\ell - T^g)) \quad (\text{IV.5b})$$

It is important to realize that Eq. (IV.5) are exactly equivalent to Eq. (IV.2). It is common to do these transformations neglecting third and higher order contributions in the deviation from equilibrium. Such approximations were not needed here.

Eq. (IV.5) has the form of the entropy production for the surface used in [3]. It was obtained there using the local equilibrium hypothesis, which we have proven to be valid in [2]. In this article we have derived Eq. (IV.5) independently, by calculating the excess of the continuous entropy production in the gradient model.

V. SURFACE TRANSFER COEFFICIENTS.

Consider Eq. (IV.5) for excess entropy production which has the form

$$\hat{\sigma}_s = J'_q X_q - \sum_{i=1}^n J_{\xi_i} X_i \quad (\text{V.1})$$

We will use the form (V.1) further, specifying the explicit expressions for fluxes and forces where needed. Following the common procedure we write the linear force-flux relations for a given entropy production:

$$\begin{aligned} X_q &= R_{qq}(T_{eq}, \psi_{eq}) J'_q + \sum_{i=1}^n R_{qi}(T_{eq}, \psi_{eq}) J_{\xi_i} \\ -X_j &= R_{jq}(T_{eq}, \psi_{eq}) J'_q + \sum_{i=1}^n R_{ji}(T_{eq}, \psi_{eq}) J_{\xi_i} \end{aligned} \quad (\text{V.2})$$

As these relations are true only to the linear order in perturbations, we must keep only linear contributions in all terms. It means that all the resistivities in Eq. (V.2) are functions of only equilibrium temperature T_{eq} and equilibrium chemical potential difference ψ_{eq} around which a particular perturbation is performed. They do not depend on the nature of the perturbation.

Consider the following matrix notation of the above quantities

$$\mathbf{X} \equiv \begin{pmatrix} X_q \\ -X_1 \\ \vdots \\ -X_n \end{pmatrix}, \quad \mathbf{R} \equiv \begin{pmatrix} R_{qq} & R_{q1} & \dots & R_{qn} \\ R_{1q} & R_{11} & \dots & R_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ R_{nq} & R_{n1} & \dots & R_{nn} \end{pmatrix}, \quad \mathbf{J} \equiv \begin{pmatrix} J'_q \\ J_{\xi_1} \\ \vdots \\ J_{\xi_n} \end{pmatrix} \quad (\text{V.3})$$

Let β indicate a measure of a non-equilibrium perturbation, so that $\mathbf{X} = \mathbf{X}(\beta)$ and $\mathbf{J} = \mathbf{J}(\beta)$. Then Eq. (V.2) can be written in a matrix form as

$$\mathbf{X}(\beta) = \mathbf{R}(T_{eq}, \psi_{eq}) \cdot \mathbf{J}(\beta) \quad (\text{V.4})$$

For big values of β Eq. (V.4) is not correct, since big perturbations are not described by the linear theory. As we decrease β , the accuracy of Eq. (V.4) increases and in the limit $\beta \rightarrow 0$ becomes exact. It means that Eq. (V.4) should be understood as

$$\lim_{\beta \rightarrow 0} \mathbf{X}(\beta) = \mathbf{R}(T_{eq}, \psi_{eq}) \cdot \lim_{\beta \rightarrow 0} \mathbf{J}(\beta) \quad (\text{V.5})$$

One should not write Eq. (V.5) in the form $\mathbf{X}(0) = \mathbf{R}(T_{eq}, \psi_{eq}) \cdot \mathbf{J}(0)$ however, as both $\mathbf{X}(0)$ and $\mathbf{J}(0)$ contain only zeroes and such an expression makes no sense. Even though $\mathbf{X}(\beta)$ and $\mathbf{J}(\beta)$ are continuous functions of β , one should write $\lim_{\beta \rightarrow 0} \mathbf{X}(\beta)$ and $\lim_{\beta \rightarrow 0} \mathbf{J}(\beta)$ instead of $\mathbf{X}(0)$ and $\mathbf{J}(0)$ respectively. In practice there exists a particular measure β_{eq} of a perturbation, such that for all $\beta < \beta_{eq}$ Eq. (V.4) is satisfied with a satisfactory accuracy.

One should also note that the accuracy of a particular numerical procedure may limit the validity of Eq. (V.5) as well. All the non-equilibrium profiles and therefore forces and fluxes are calculated by solving the system of differential equations numerically with some particular accuracy. If a perturbation rate is lower then this accuracy, say β_{num} , the data obtained from the numerical procedure are not reliable. Performing a numerical analysis we must therefore replace the limiting value 0 by β_{num} in Eq. (V.5).

As shown by Onsager [21], the cross coefficients must be the same. We therefore have

$$\begin{aligned} R_{qi} &= R_{iq} \\ R_{ji} &= R_{ij} \end{aligned} \quad (\text{V.6})$$

A. Gas- and liquid- side transport coefficients.

For each of Eq. (IV.5) one might associate the forces with

$$\begin{aligned} X_q^g &= X_q^\ell \equiv \frac{1}{T^\ell} - \frac{1}{T^g} \\ X_j^g &\equiv \frac{1}{T^\ell} (\tilde{\mu}_j^\ell - \tilde{\mu}_j^g + s_j^g(T^\ell - T^g)) \\ X_j^\ell &\equiv \frac{1}{T^g} (\tilde{\mu}_j^\ell - \tilde{\mu}_j^g + s_j^\ell(T^\ell - T^g)) \end{aligned} \quad (\text{V.7})$$

As we are in the context of the linear theory, however, we must linearize these forces with respect to the perturbation and discard all higher order terms. Leaving them would not increase accuracy but may affect the consistency of the linear theory. We therefore get the following phenomenological relations up to the linear order

$$\begin{aligned} \frac{1}{T^\ell} - \frac{1}{T^g} &= R_{qq}^g J_q'^{g} + \sum_{i=1}^n R_{qi}^g J_{\xi_i} \\ -\frac{1}{T_{eq}} (\tilde{\mu}_j^\ell - \tilde{\mu}_j^g + s_{j,eq}^g(T^\ell - T^g)) &= R_{jq}^g J_q'^{g} + \sum_{i=1}^n R_{ji}^g J_{\xi_i} \end{aligned} \quad (\text{V.8})$$

and

$$\begin{aligned} \frac{1}{T^\ell} - \frac{1}{T^g} &= R_{qq}^\ell J_q'^{\ell} + \sum_{i=1}^n R_{qi}^\ell J_{\xi_i} \\ -\frac{1}{T_{eq}} (\tilde{\mu}_j^\ell - \tilde{\mu}_j^g + s_{j,eq}^\ell (T^\ell - T^g)) &= R_{jq}^\ell J_q'^{\ell} + \sum_{i=1}^n R_{ji}^\ell J_{\xi_i} \end{aligned} \quad (\text{V.9})$$

Here and after we omit arguments (T_{eq}, ψ_{eq}) as long as it does not lead to confusion.

The measurable heat fluxes are related by Eq. (IV.4) which after linearization takes the following form

$$J_q'^g - J_q'^\ell = \sum_{i=1}^n J_{\xi_i} (\tilde{h}_{i,eq}^\ell - \tilde{h}_{i,eq}^g) \quad (\text{V.10})$$

Comparing Eq. (V.8) and Eq. (V.9) and using Eq. (V.10) we get the following relations between the coefficients associated with the gas and liquid measurable heat fluxes to linear order

$$\begin{aligned} R_{qq}^\ell &= R_{qq}^g \\ R_{qi}^\ell - h_{i,eq}^\ell R_{qq}^\ell &= R_{qi}^g - h_{i,eq}^g R_{qq}^g \\ R_{iq}^\ell - h_{i,eq}^\ell R_{qq}^\ell &= R_{iq}^g - h_{i,eq}^g R_{qq}^g \\ R_{ji}^\ell - h_{i,eq}^\ell R_{jq}^\ell - h_{j,eq}^\ell R_{qi}^\ell + h_{i,eq}^\ell h_{j,eq}^\ell R_{qq}^\ell &= R_{ji}^g - h_{i,eq}^g R_{jq}^g - h_{j,eq}^g R_{qi}^g + h_{i,eq}^g h_{j,eq}^g R_{qq}^g \end{aligned} \quad (\text{V.11})$$

where we took into account that $\tilde{\mu}_{i,eq}^g = \tilde{\mu}_{i,eq}^\ell$ and $\tilde{h}_{i,eq}^g - \tilde{h}_{i,eq}^\ell = h_{i,eq}^g - h_{i,eq}^\ell$.

The coefficients on the one side determine uniquely the coefficients on the other side, having the values of jumps across the surface of the extrapolated enthalpies. It follows from Eq. (V.11) that

$$\begin{aligned} R_{qq}^\ell &= R_{qq}^g \\ R_{qi}^\ell &= R_{qi}^g - (h_{i,eq}^g - h_{i,eq}^\ell) R_{qq}^g \\ R_{iq}^\ell &= R_{iq}^g - (h_{i,eq}^g - h_{i,eq}^\ell) R_{qq}^g \\ R_{ji}^\ell &= R_{ji}^g - (h_{i,eq}^g - h_{i,eq}^\ell) R_{jq}^g - (h_{j,eq}^g - h_{j,eq}^\ell) R_{qi}^g + (h_{i,eq}^g - h_{i,eq}^\ell) (h_{j,eq}^g - h_{j,eq}^\ell) R_{qq}^g \end{aligned} \quad (\text{V.12})$$

One can notice, that symmetry of R^g coefficients implies the same symmetry of R^ℓ coefficients and vice versa.

To avoid confusion we recall that for the temperature T , chemical potential μ_j and the partial entropy s_j the superscript g or ℓ means the value of the corresponding function extrapolated from either gas or liquid to the interfacial region and evaluated at a particular dividing surface x^s . We do not indicate which dividing surface is used as it is irrelevant for the present analysis. In contrast, $J_q'^g \equiv J_e - \sum_{i=1}^n \tilde{h}_i(x^{g,s}) J_{\xi_i}$ where the partial enthalpy is evaluated at the gas-surface boundary $x^{g,s}$. To the linear order however $\tilde{h}_i(x^{g,s}) = \tilde{h}_{i,eq}(x^{g,s}) = \tilde{h}_{i,eq}^g(x^s) \equiv \tilde{h}_{i,eq}^g$ and since J_e and J_{ξ_i} are constants, $J_q'^g$ may be considered as the flux, evaluated at a dividing surface x^s . Furthermore, superscript g or ℓ for the resistivity R^g or R^ℓ neither indicate any position nor the extrapolated resistivity coefficient. It indicates the measurable heat flux with which the given resistivity coefficient is associated, either $J_q'^g$ or $J_q'^\ell$ respectively.

B. Mass and molar transport coefficients.

In applications it is common to use the mass flux of the components and the partial molar thermodynamic quantities, like, for instance, partial molar entropy. The above equations should use either molar fluxes and partial molar thermodynamic quantities or mass fluxes and partial mass thermodynamic quantities. The transport coefficients are different for different choices. Consider Eq. (V.1) for excess entropy production. The thermodynamic forces X_i depend on partial thermodynamic quantities. We introduce therefore X_i^m as a force which uses partial mass quantities and X_i^ν as a force which uses partial molar quantity. Furthermore, let $J_{\xi_i} \equiv \rho_i v_i$ and $J_{\zeta_i} \equiv c_i v_i$ be the mass and molar

flux respectively of the i -th component. As $X_i^m = X_i^\nu/M_i$ and $J_{\xi_i} = J_{\zeta_i}M_i$, where M_i is the molar mass of the i -th component, the excess entropy production becomes

$$\hat{\sigma}_s = J'_q X_q - \sum_{i=1}^n J_{\xi_i} X_i^m = J'_q X_q - \sum_{i=1}^n J_{\zeta_i} X_i^\nu \quad (\text{V.13})$$

The force-flux relations become

$$\begin{aligned} X_q &= R_{qq}^m J'_q + \sum_{i=1}^n R_{qi}^m J_{\xi_i} \\ -X_j^m &= R_{jq}^m J'_q + \sum_{i=1}^n R_{ji}^m J_{\xi_i} \end{aligned} \quad (\text{V.14a})$$

and

$$\begin{aligned} X_q &= R_{qq}^\nu J'_q + \sum_{i=1}^n R_{qi}^\nu J_{\zeta_i} \\ -X_j^\nu &= R_{jq}^\nu J'_q + \sum_{i=1}^n R_{ji}^\nu J_{\zeta_i} \end{aligned} \quad (\text{V.14b})$$

where the corresponding superscript for the resistivity coefficient indicates the association with the mass or molar quantities. These transport coefficients are related in the following way

$$\begin{aligned} R_{qq}^\nu &= R_{qq}^m \\ R_{qi}^\nu &= M_i R_{qi}^m \\ R_{iq}^\nu &= M_i R_{iq}^m \\ R_{ji}^\nu &= M_j M_i R_{ji}^m \end{aligned} \quad (\text{V.15})$$

VI. TWO COMPONENT MIXTURE.

We now restrict ourselves to the mixture considered in [2]. We consider the mixture of cyclohexane (1st component) and n -hexane (2nd component) in a box with gravity directed along axes x from left to right. The gas phase is therefore in the left part of the box and the liquid is in the right part of the box. The surface is planar.

We have the following expression for the excess entropy production

$$\hat{\sigma}_s = J'_q X_q - J_{\xi_1} X_1 - J_{\xi_2} X_2 \quad (\text{VI.1})$$

and force-flux relations (V.4) with

$$\mathbf{X} \equiv \begin{pmatrix} X_q \\ -X_1 \\ -X_2 \end{pmatrix}, \quad \mathbf{R} \equiv \begin{pmatrix} R_{qq} & R_{q1} & R_{q2} \\ R_{1q} & R_{11} & R_{12} \\ R_{2q} & R_{21} & R_{22} \end{pmatrix}, \quad \mathbf{J} \equiv \begin{pmatrix} J'_q \\ J_{\xi_1} \\ J_{\xi_2} \end{pmatrix} \quad (\text{VI.2})$$

We will also use an alternative expression for the excess entropy production, which uses the total mass flux $J_m = J_{\xi_1} + J_{\xi_2}$ and the flux of one of the components, say $J_{\xi_1} \equiv J_\xi$:

$$\hat{\sigma}_s = J'_q X_q - J_\xi X_\xi - J_m X_m \quad (\text{VI.3})$$

where $X_\xi \equiv X_1 - X_2$ and $X_m \equiv X_2$. The resulting force-flux relations (V.4) have the following terms

$$\mathbf{X} \equiv \begin{pmatrix} X_q \\ -X_\xi \\ -X_m \end{pmatrix}, \quad \mathbf{R} \equiv \begin{pmatrix} R_{qq} & R_{q\xi} & R_{qm} \\ R_{\xi q} & R_{\xi\xi} & R_{\xi m} \\ R_{mq} & R_{m\xi} & R_{mm} \end{pmatrix}, \quad \mathbf{J} \equiv \begin{pmatrix} J'_q \\ J_\xi \\ J_m \end{pmatrix} \quad (\text{VI.4})$$

where the coefficients from Eq. (VI.2) are related to the coefficients from Eq. (VI.4) as

$$\begin{aligned} R_{q1} &= R_{q\xi} + R_{qm} & R_{11} &= -R_{m\xi} - R_{\xi m} + R_{mm} + R_{\xi\xi} \\ R_{1q} &= R_{\xi q} + R_{mq} & R_{22} &= R_{mm} \\ R_{q2} &= R_{qm} & R_{12} &= R_{mm} - R_{\xi m} \\ R_{2q} &= R_{mq} & R_{21} &= R_{mm} - R_{m\xi} \end{aligned} \quad (\text{VI.5})$$

Having the numerical solution for a particular non-equilibrium stationary state we know all the fluxes J and forces X used in Eq. (V.4): the constant fluxes are obtained directly from the non-equilibrium solution and the extrapolated bulk profiles are obtained using the procedure described in [2]. On the other hand we know only the local resistivities but not the resistivities R of the whole surface.

We now consider the inverse problem: to determine the transport coefficients for the whole surface having the non-equilibrium solution. As one can see, Eq. (V.4) has 9 unknown resistivities⁴ and only 3 equations. It is therefore not possible to determine all the transport coefficients uniquely having only one stationary state solution. In order to incorporate more equations we need to consider other non-equilibrium stationary solutions which are independent of the previous. As the transport coefficients depend only on equilibrium unperturbed state but not on non-equilibrium perturbations, considering different perturbations around the same equilibrium state we will get missing data. We must ensure however, that a given perturbation is small enough to be described by linear-order equations. This would require for instance Eq. (V.6) and Eq. (V.11) to be true. There are more constraints to be fulfilled which will be discussed in Sec. [VIII].

The non-equilibrium solution uses following profiles for local resistivities (see [2] for details)

$$\begin{aligned} r_{qq}(x) &= r_{qq}^g + (r_{qq}^\ell - r_{qq}^g) q_0(x) + \alpha_{qq}(r_{qq}^\ell + r_{qq}^g) q_1(x) \\ r_{q1}(x) &= r_{q1}^g + (r_{q1}^\ell - r_{q1}^g) q_0(x) + \alpha_{q1}(r_{q1}^\ell + r_{q1}^g) q_1(x) \\ r_{11}(x) &= r_{11}^g + (r_{11}^\ell - r_{11}^g) q_0(x) + \alpha_{11}(r_{11}^\ell + r_{11}^g) q_1(x) \end{aligned} \quad (\text{VI.6})$$

where $q_0(x)$ and $q_1(x)$ are modulatory curves for resistivity profiles which depend only on density profiles and their first derivatives. For each resistivity profile r^g and r^ℓ are the equilibrium coexistence resistivities of the gas and liquid phase respectively. Coefficients α_{qq} , α_{q1} , α_{11} control the size of the peak in the resistivity profiles in the interfacial region. The non-equilibrium stationary state depends on the values of these coefficients. The surface resistivity coefficients R will therefore depend on these coefficients as on parameters, $R = R(\alpha_{qq}, \alpha_{q1}, \alpha_{11})$, which we will investigate.

VII. METHODS TO OBTAIN RESISTIVITIES.

We determine the transport coefficients from three different methods: from a "perturbation cell" method⁵, from an experimental-like procedure and from kinetic theory.

A. Perturbation cell.

Consider a stationary state which is perturbed from equilibrium by setting the temperature of the liquid⁶ $T(x^\ell) = (1 + \beta_T)T_{eq}$, the pressure of the gas $p(x^g) = (1 + \beta_p)p_{eq}$ and the mole fraction of the liquid $\zeta^\ell(x^\ell) = (1 + \beta_\zeta)\zeta_{eq}^\ell$ independently. The resulting non-equilibrium state is therefore a function of parameters β :

$$X(\beta_T, \beta_p, \beta_\zeta) = R(T_{eq}, \psi_{eq}) \cdot J(\beta_T, \beta_p, \beta_\zeta) \quad (\text{VII.1})$$

where X , J and R are given by Eq. (VI.2). Consider the following set of 8 independent non-equilibrium perturbations:

$$\begin{aligned} X(\beta, \beta, \beta) &= R(T_{eq}, \psi_{eq}) \cdot J(\beta, \beta, \beta) \\ X(\beta, -\beta, \beta) &= R(T_{eq}, \psi_{eq}) \cdot J(\beta, -\beta, \beta) \\ X(-\beta, \beta, \beta) &= R(T_{eq}, \psi_{eq}) \cdot J(-\beta, \beta, \beta) \\ X(-\beta, -\beta, \beta) &= R(T_{eq}, \psi_{eq}) \cdot J(-\beta, -\beta, \beta) \\ X(\beta, \beta, -\beta) &= R(T_{eq}, \psi_{eq}) \cdot J(\beta, \beta, -\beta) \\ X(\beta, -\beta, -\beta) &= R(T_{eq}, \psi_{eq}) \cdot J(\beta, -\beta, -\beta) \\ X(-\beta, \beta, -\beta) &= R(T_{eq}, \psi_{eq}) \cdot J(-\beta, \beta, -\beta) \\ X(-\beta, -\beta, -\beta) &= R(T_{eq}, \psi_{eq}) \cdot J(-\beta, -\beta, -\beta) \end{aligned} \quad (\text{VII.2})$$

⁴ Solving the inverse problem we have to proof the Onsager reciprocal relations rather than impose them.

⁵ This method was first used by Johannessen et. al. in [17] for one-component system. Here we discuss the grounds for the legitimacy of this procedure and generalize it to mixtures.

⁶ One should not confuse $T(x^\ell)$ with T^ℓ . The former is the actual temperature at $x = x^\ell$, i.e. at the box boundary on the liquid side. The latter is the temperature extrapolated from the liquid phase to the interfacial region and taken at $x = x^s$, i.e. at the dividing surface.

Consider now the 3×8 matrices $\mathfrak{X}$ and $\mathfrak{J}$ which contain 8 column vectors X and J respectively for each non-equilibrium perturbation specified above. For these perturbations $\mathfrak{X} = \mathfrak{X}(\beta)$ and $\mathfrak{J} = \mathfrak{J}(\beta)$ are the functions only on one parameter β . It follows from Eq. (VII.2) that

$$\mathfrak{X}(\beta) = R(T_{eq}, \psi_{eq}) \cdot \mathfrak{J}(\beta) \quad (\text{VII.3})$$

As it was discussed in Sec. [V], for practical purposes these limits should be calculated as the values of corresponding matrices at very small but finite value of β . $R(T_{eq}, \psi_{eq})$ depends therefore on β and we will keep it as an argument. From Eq. (VII.3) we obtain

$$R(T_{eq}, \psi_{eq}; \beta) = (\mathfrak{X}(\beta) \cdot \mathfrak{J}^T(\beta)) \cdot (\mathfrak{J}(\beta) \cdot \mathfrak{J}^T(\beta))^{-1} \quad (\text{VII.4})$$

where superscript T means the matrix transpose and $^{-1}$ means the inverted matrix.

We note, that in order to obtain the resistivity matrix R uniquely, it is sufficient in principle to impose any 3 non-equilibrium perturbations which have sufficiently small perturbation parameters β_T , β_p and β_ζ . As *each* of β_T , β_p and β_ζ goes to zero the resistivity matrix will go to $R(T_{eq}, \psi_{eq})$ as fast as *all* β_T , β_p and β_ζ go to zero. The method presented above makes the resistivity matrix converge to $R(T_{eq}, \psi_{eq})$ as fast as β^2 goes to zero, however. This is achieved by using 8 perturbations at the "corners" of a three-dimensional "perturbation cell", so changing β to $-\beta$ would not change the "perturbation cell" and the resulting R .

Because of using 8 perturbations instead of 3, there are 5 superfluous perturbations which make the system of equations (VII.3) to be overdetermined. Contracting both sides of Eq. (VII.3) with $\mathfrak{J}^T$ we actually average all the perturbations which are spread around T_{eq} and ψ_{eq} in the least square sense. As the components of $\mathfrak{J}$ matrix are linearly independent, this guarantees the matrix $\mathfrak{J} \cdot \mathfrak{J}^T$ to be invertible. Thus, the inverse matrix $(\mathfrak{J} \cdot \mathfrak{J}^T)^{-1}$ exists and Eq. (VII.4) is mathematically legitimate. In the numerical procedure the expression on the right hand side of Eq. (VII.4) is obtained using Matlab matrix division $\mathfrak{X} \backslash \mathfrak{J}$.

B. Experiment-like procedure.

In experiments it is convenient to measure the corresponding coefficients by keeping zero mass fluxes through the system. It is also convenient to work with the total mass flux J_m and the flux of one of the components J_ξ , rather than with fluxes of each component separately⁷, J_{ξ_1} and J_{ξ_2} .

Consider a stationary state which is perturbed from equilibrium by setting the temperature of the liquid $T(x^\ell) = (1 + \beta_T)T_{eq}$. The second perturbation condition is either $J_\xi = 0$ or $\zeta^\ell(x^\ell) = \zeta_{eq}^\ell$ and we introduce the perturbation parameter β_ξ which is 0 in the former case and 1 in the latter one. The third perturbation condition is either $J_m = 0$ or $p(x^g) = p_{eq}$ and the corresponding perturbation parameter β_m is 0 or 1 respectively. The resulting non-equilibrium state is therefore a function of 3 parameters:

$$X(\beta_T, \beta_\xi, \beta_m) = R(T_{eq}, \psi_{eq}) \cdot J(\beta_T, \beta_\xi, \beta_m) \quad (\text{VII.5})$$

where X , J and R are given by Eq. (VI.4). Consider the following set of 3 independent non-equilibrium perturbations:

$$\begin{aligned} X(\beta, 0, 0) &= R(T_{eq}, \psi_{eq}) \cdot J(\beta, 0, 0) \\ X(\beta, 1, 0) &= R(T_{eq}, \psi_{eq}) \cdot J(\beta, 1, 0) \\ X(\beta, 1, 1) &= R(T_{eq}, \psi_{eq}) \cdot J(\beta, 1, 1) \end{aligned} \quad (\text{VII.6})$$

From the first of Eq. (VII.6) we find

$$\begin{aligned} R_{qq}(T_{eq}, \psi_{eq}) &= X_{q, 00} / J'_{q, 00} \\ R_{\xi q}(T_{eq}, \psi_{eq}) &= X_{\xi, 00} / J'_{q, 00} \\ R_{mq}(T_{eq}, \psi_{eq}) &= X_{m, 00} / J'_{q, 00} \end{aligned} \quad (\text{VII.7a})$$

where we use subscripts $\beta_\xi \beta_m$ instead the functional dependence $(\beta, \beta_\xi, \beta_m)$ for simplicity of notation. From the second of Eq. (VII.6) we find

$$\begin{aligned} R_{q\xi}(T_{eq}, \psi_{eq}) &= (X_{q, 10} - R_{qq}(T_{eq}, \psi_{eq}) J'_{q, 10}) / J_{\xi, 10} \\ R_{\xi\xi}(T_{eq}, \psi_{eq}) &= (X_{\xi, 10} - R_{\xi q}(T_{eq}, \psi_{eq}) J'_{q, 10}) / J_{\xi, 10} \\ R_{m\xi}(T_{eq}, \psi_{eq}) &= (X_{m, 10} - R_{mq}(T_{eq}, \psi_{eq}) J'_{q, 10}) / J_{\xi, 10} \end{aligned} \quad (\text{VII.7b})$$

⁷ One of the reasons for this is that it is hard to make only $J_{\xi_1} = 0$, keeping J_{ξ_2} finite.

The values X_{10} and J_{10} are found directly from the calculations and the values of $R_{qq}(T_{eq}, \psi_{eq})$, $R_{\xi q}(T_{eq}, \psi_{eq})$ and $R_{mq}(T_{eq}, \psi_{eq})$ are those which are found in Eq. (VII.7a), given the perturbation rate β is small enough. From the third of Eq. (VII.6) we find

$$\begin{aligned} R_{qm}(T_{eq}, \psi_{eq}) &= (X_{q, 11} - R_{qq}(T_{eq}, \psi_{eq}) J'_{q, 11} - R_{q\xi}(T_{eq}, \psi_{eq}) J_{\xi, 11}) / J_{m, 11} \\ R_{\xi m}(T_{eq}, \psi_{eq}) &= (X_{\xi, 11} - R_{\xi q}(T_{eq}, \psi_{eq}) J'_{q, 11} - R_{\xi\xi}(T_{eq}, \psi_{eq}) J_{\xi, 11}) / J_{m, 11} \\ R_{mm}(T_{eq}, \psi_{eq}) &= (X_{m, 11} - R_{mq}(T_{eq}, \psi_{eq}) J'_{q, 11} - R_{m\xi}(T_{eq}, \psi_{eq}) J_{\xi, 11}) / J_{m, 11} \end{aligned} \quad (\text{VII.7c})$$

Again, all the quantities on the right hand side of Eq. (VII.7c) are known and we therefore can find the remaining resistivities.

C. Comparison to kinetic theory.

According to [3, p. 180] kinetic theory gives the following expressions for the surface transport coefficients for two component mixture

$$\begin{aligned} R_{qq}^{g, \nu}(T, \psi) &= 4 R_O(T, \psi) \left\{ 1 + \frac{104}{25\pi} \left(\frac{w_1^2}{\varsigma_1} + \frac{w_2^2}{\varsigma_2} \right) \right\} \\ R_{qi}^{g, \nu}(T, \psi) = R_{iq}^{g, \nu}(T, \psi) &= 2RT R_O(T, \psi) \left\{ 1 + \frac{16}{5\pi} \frac{w_i}{\varsigma_i} \right\} \\ R_{ij}^{g, \nu}(T, \psi) &= (RT)^2 R_O(T, \psi) \left\{ 1 + 32 \delta_{ij} \frac{1}{\varsigma_i} \left(\frac{1}{\sigma_i} + \frac{1}{\pi} - \frac{3}{4} \right) \right\} \end{aligned} \quad (\text{VII.8})$$

where

$$\begin{aligned} R_O(T, \psi) &\equiv 2^{-9/2} \sqrt{\pi} R (RT)^{-5/2} (c_1^g / \sqrt{M_1} + c_2^g / \sqrt{M_2})^{-1} \\ \varsigma_i(T, \psi) &\equiv (c_i^g / \sqrt[4]{M_i}) / (c_1^g / \sqrt[4]{M_1} + c_2^g / \sqrt[4]{M_2}) \\ w_i(T, \psi) &\equiv \lambda_i / (\lambda_1 + \lambda_2) \end{aligned} \quad (\text{VII.9})$$

where R is universal gas constant, λ_i and $c_{i,eq}^g$ are the thermal conductivity and the gas coexistence concentration of i -th component respectively. σ_i is the condensation coefficient, which is parameter in this theory and δ_{ij} is the Kroneker symbol.

VIII. RESULTS.

Using the procedures described above we obtain different sets of transport coefficients $R(T, \psi)$, each of them as a function of equilibrium temperature and chemical potential difference. Let us use subscript pc for the resistivity matrix obtained from the "perturbation cell" method and ex for the resistivity matrix obtained from the "experiment-like" method. In each method we calculate the resistivities associated with the gas- and liquid- side measurable heat fluxes using Eq. (V.8) and Eq. (V.9).

Furthermore we will use subscript kin for the resistivity matrix obtained from kinetic theory, for which only the gas- side resistivities are available. We calculate the transport coefficients associated only with mass properties. The corresponding molar coefficients may be calculated using Eq. (V.15). As a result we obtain the following sets of resistivities: R_{pc}^g , R_{pc}^ℓ , R_{ex}^g , R_{ex}^ℓ , all of which depend on temperature and chemical potential difference as well as on parameters α_{qq} , α_{1q} , α_{11} . In addition we obtain R_{kin}^g which depend on temperature and chemical potential difference as well as on condensation coefficients σ_1 and σ_2 . We have the following constraints, which they must obey for each T and ψ :

- i) the second law consistency;
- ii) the cross coefficients of each R matrix must satisfy Onsager relations (V.6);
- iii) the corresponding components of R_{pc}^g and R_{pc}^ℓ as well as R_{ex}^g and R_{ex}^ℓ must satisfy Eq. (V.11);
- iv) the corresponding components of R_{pc}^g , R_{ex}^g and R_{kin}^g as well as R_{pc}^ℓ and R_{ex}^ℓ obtained at the same T and ψ must be equal.

We study the dependence of the different resistivity coefficients on α_{qq} , α_{1q} and α_{11} and on T and ψ and their convergence for small β . We determine the values of the parameters for which the above constraints are fulfilled.

A. Onsager reciprocal relations.

In this subsection we investigate the values of parameters α_{qq} , α_{1q} , α_{11} for which the Onsager relations are fulfilled. This is done for a particular values of equilibrium temperature and chemical potential difference $T_{eq} = 330$ K and $\psi_{eq} = 700$ J/mol. In Tables [I-II] we give the relative error in percent for the gas-side cross coefficients $|(R_{ij}^g - R_{ji}^g)/R_{ij}^g| \cdot 100\%$ as a function of β for $\alpha_{qq} = 0$, $\alpha_{1q} = 0$, $\alpha_{11} = 0$ obtained by different methods.

TABLE I: Relative error in percent for gas-side cross-coefficients obtained by "perturbation cell" method at $T_{eq} = 330$ and $\psi_{eq} = 700$ for different β and for $\alpha_{qq} = 0$, $\alpha_{1q} = 0$, $\alpha_{11} = 0$.

β	R_{q1}	R_{q2}	R_{12}

2.0e-006	13.282959	20.788752	632.124504

As one can see, $\beta = 0.02$ is really an extreme perturbation and the difference is rather large. When we decrease β to $2e-4$ the differences become small. As we further decrease β to $2e-6$ the inaccuracy of the numerical solution become comparable to the size of the perturbation. We conclude that the values for β to $2e-4$ are closest to the converged values and use them as such.

In Tables [III-IV] we give the same data for the higher continuous resistivities with rather substantial peak, when $\alpha_{qq} = 10$, $\alpha_{1q} = 10$ and $\alpha_{11} = 10$. As one can see, the Onsager relations are fulfilled there again best for $\beta = 2e-4$

TABLE III: Relative error in percent for gas-side cross-coefficients obtained by "perturbation cell" method at $T_{eq} = 330$ and $\psi_{eq} = 700$ for different β and for $\alpha_{qq} = 10$, $\alpha_{1q} = 10$, $\alpha_{11} = 10$.

2.0e-006	2.717575	4.149484	2.025054

The similar picture is observed for the liquid-side resistivities and we do not give those data here.

We may notice that the behavior of the resistivities with respect to β is independent on the behavior of the resistivities with respect to α_{qq} , α_{1q} and α_{11} . This is natural, as these parameters control the different aspects of the system: β controls the perturbation rate, while α 's are adjustable parameters, which control the size of the peak in the continuous resistivities.

B. Second law consistency.

In this subsection we investigate the values of parameters α_{qq} , α_{1q} , α_{11} for which the second law of thermodynamics are fulfilled. That is that the excess entropy production is positive and therefore the matrix of the resistivity coefficients is positive definite. This requires that the diagonal coefficients are positive and for each pair $q1$, $q2$ and 12 of the cross coefficients the expression

$$DR_{ik} \equiv R_{ii}R_{kk} - \frac{1}{4}(R_{ik} + R_{ki})^2 > 0 \quad (\text{VIII.1})$$

must be positive.

In Table [V] we give the diagonal coefficients and expression (VIII.1) for each pair of the cross coefficients as a function of α_{qq} for $\alpha_{1q} = 0$, $\alpha_{11} = 0$ and $\beta = 2\text{e-}4$ obtained by the "perturbation cell" method. In Tables [VI-VII] we give the same quantities for other choices of α .

TABLE V: 2nd law consistency for gas-side coefficients. The diagonal coefficients and the quantities defined by (VIII.1). Data are obtained by "perturbation cell" method at $T_{eq} = 330$ and $\psi_{eq} = 700$ for different α_{qq} and for $\beta = 0.0002$, $\alpha_{1q} = 0$, $\alpha_{11} = 0$.

TABLE VII: 2nd law consistency for gas-side coefficients. The diagonal coefficients and the quantities defined by (VIII.1). Data are obtained by "perturbation cell" method at $T_{eq} = 330$ and $\psi_{eq} = 700$ for different α_{11} and for $\beta = 0.0002$, $\alpha_{qq} = 0$, $\alpha_{1q} = 0$.

α_{11}	R_{qq}	R_{11}	R_{22}	DR_{q1}	DR_{q2}	DR_{12}
0	7.05644e-015	0.0754717	-0.0919278	2.13025e-015	-2.59473e-015	-0.0277518
1	7.05717e-015	0.370078	0.265626	1.04468e-014	7.49827e-015	0.381226
10	7.10378e-015	3.02063	3.48284	8.58316e-014	9.89654e-014	-69.2846

We see, that the required quantities become positive for rather big values of α_{qq} . They almost do not depend on the value of α_{1q} and they are positive for moderate values of parameter α_{11} . It is clear that finite values of α_{qq} and α_{11} are needed to have a positive excess entropy production.

All the above quantities almost do not depend on the value of β in the range $[1\text{e-}5, 1\text{e-}3]$. The "experimental-like" procedure leads to almost the same values of all the quantities. The liquid-side coefficients reveal a similar behavior.

C. Gas- and liquid- coefficients.

In this subsection we investigate the validity of Eq. (V.11). In Table [VIII] we give the relative error in percent between the left hand side and the right hand side of Eq. (V.11).

TABLE VIII: Relative error in percent for invariant expressions in Eq. (V.11) obtained by "perturbation cell" method at $T_{eq} = 330$ and $\psi_{eq} = 700$ for $\beta = 0.0002$ and $\alpha_{qq} = 1$, $\alpha_{1q} = 1$, $\alpha_{11} = 1$.

qq	11	22	$q1$	$1q$	$q2$	$2q$	12	21
0.000000	0.000002	0.000085	0.000001	0.000389	0.000001	0.000389	0.000060	0.000003

For instance, the $q1$ quantity is equal to $|(R_{q1}^\ell - h_{1,eq}^\ell R_{qq}^\ell) - (R_{q1}^g - h_{1,eq}^g R_{qq}^g)| / |R_{q1}^\ell - h_{1,eq}^\ell R_{qq}^\ell| \cdot 100\%$. The other quantities are defined in the same way. These errors almost do not depend neither on the value of β in the range $[1e-5, 1e-3]$ nor on the values of α_{qq} , α_{1q} , α_{11} . The "experimental-like" procedure leads to almost the same results.

D. Comparison to kinetic theory.

In this subsection we investigate the values of parameters α_{qq} , α_{1q} , α_{11} which makes the coefficients agree with the kinetic theory coefficients. We do it for $\beta = 2e-4$ as this perturbation rate gives the most accurate results. We again do this for temperature $T_{eq} = 330$ K and chemical potential difference $\psi_{eq} = 700$ J/mol. The values of parameters, used for kinetic theory are the same, as we use in our calculations. Particularly, the heat conductivities are $\lambda_1 = 0.0140$ W/(m K) and $\lambda_2 = 0.0157$ W/(m K), $M_1 = 84.162$ g/mol and $M_2 = 86.178$ g/mol. We compare here only the "perturbation cell" method with kinetic theory.

We found that the variation of α_{1q} from 0 to 10 makes the diagonal coefficients vary about 1% and the cross coefficients vary not more than 5%. As the variation of α_{1q} is quite substantial, the variation in the coefficients which it induces is negligible. We therefore take $\alpha_{1q} = 0$ in all further analysis.

For the above parameters $R_{qq,kin} = 2.96792 \times 10^{-11}$. We found that $R_{qq,pc}$ is practically independent on α_{11} while it depends linearly on α_{qq} , see Fig. [1]. One can see from the plot, that $R_{qq,kin} = R_{qq,pc}$ for $\alpha_{qq} \approx 9$.

FIG. 1: Dependence of R_{qq} on α_{qq} obtained by "perturbation cell" method at $T_{eq} = 330$ and $\psi_{eq} = 700$ for $\alpha_{1q} = 0$ and $\alpha_{11} = 1$. $R_{qq,kin}$ is drawn as a constant line.

The diagonal coefficients $R_{11,pc}$ and $R_{22,pc}$ depend both on α_{qq} and α_{11} . Since we have found the corresponding to kinetic theory value of α_{qq} by mapping the R_{qq} coefficient, we will further investigate the dependence of $R_{11,pc}$ and $R_{22,pc}$ using this value of α_{qq} and varying only α_{11} . The diagonal coefficients $R_{11,kin}$ and $R_{22,kin}$ depend, in their turn, on the condensation coefficients σ_1 and σ_2 respectively. We plot this dependence in the same plot with the dependency of $R_{ii,pc}$ on α_{11} , see Fig. [2]. The dependence of $R_{ii,pc}$ on α_{11} is given by the dotted line with the values of α_{11} drawn on the bottom x -axes. The dependence of $R_{ii,kin}$ on σ_i is given by the solid line with the values σ_i drawn on the top x -axes.

Consider a particular value $R_{ii,0}$ of the diagonal coefficient R_{ii} , where i is either 1 or 2, which is indicated by a horizontal dashed line on a figure. To find the value of α_{11} for which $R_{ii,pc} = R_{ii,0}$ we draw a perpendicular from the

FIG. 2: Dependence of $R_{11,pc}$ and $R_{22,pc}$ on α_{11} (dots, bottom axes) and $R_{11,kin}$ and $R_{22,kin}$ on σ_1 and σ_2 (curve, top axes), respectively. Data are obtained at $T_{eq} = 330$ and $\psi_{eq} = 700$ for $\alpha_{qq} = 9$ and $\alpha_{1q} = 0$.

point where it crosses the dotted line to the bottom axes. To find the value of σ_i for which $R_{ii,kin} = R_{ii,0}$ we draw a perpendicular from the point where the horizontal dashed line crosses the solid line to the top axes. For instance, the value $R_{22,0} = 1.1$ corresponds to $\alpha_{11} = 3$ and $\sigma_2 = 0.62$. The value $\alpha_{11} = 3$, in its turn, gives $R_{11,0} = 1.1$ which corresponds to $\sigma_1 = 0.54$.

One may start by specifying α_{11} , rather than $R_{ii,0}$, to find σ_1 and σ_2 . Then we draw a perpendicular from the bottom axes until it crosses the dotted line, which gives the value $R_{ii,0}$ of $R_{ii,pc}$. Given the value of $R_{ii,kin}$ to be the same, we find the value of σ_i as described above. For the above example $\alpha_{11} = 3$ corresponds to $\sigma_1 = 0.54$ and $\sigma_2 = 0.62$. We see, that we may not specify both σ_1 and σ_2 independently: they must have the values which both correspond to the same α_{11} . For similar components, like those we are interested in, σ_1 and σ_2 should not differ much from each other, and therefore α_{11} , a coefficient which is related to the diffusion of one component through the other, should reflect this difference.

Having the diagonal coefficient mapped we have the parameters α_{qq} and α_{11} defined uniquely (and taking into account that α_{1q} has negligible effect), as well as σ_1 and σ_2 for kinetic theory. We now compare the values of the cross coefficients given by "perturbation cell" method and kinetic theory.

TABLE IX: Gas-side transport coefficients obtained from kinetic theory and by "perturbation cell" method at $T_{eq} = 330$ and $\psi_{eq} = 700$ for $\beta = 0.0002$.

parameters	R_{qq}	R_{11}	R_{22}	R_{q1}	R_{q2}	R_{12}
$\sigma_1 = 0.54$						
$\sigma_2 = 0.62$	2.96792e-011	1.11091	1.09136	3.82826e-007	4.41483e-007	0.0130511
$\alpha_{qq} = 9$						
$\alpha_{1q} = 0$	3.01874e-011	1.12461	1.13991	2.31477e-006	2.27003e-006	-0.816559
$\alpha_{11} = 3$						

One can see from Table [IX] that while the diagonal coefficients are the same⁸, the cross coefficients we find are between 1-2 orders of magnitude larger than those found by kinetic theory. R_{12} even has a different sign.

⁸ One should not expect exact compatibility between kinetic theory, which is most appropriate for gases with short range potentials, and the gradient theory, which is most appropriate for fluids with long range potentials. The purpose of this comparison is not to determine the exact values of adjustable parameters, but to show that it is possible to match coefficients in the two theories and to show the typical values of the parameters.

E. Temperature and chemical potential difference dependence.

In this subsection we investigate the dependence of the resistivity coefficients on the temperature and the chemical potential difference. On Fig. [3-5] we plot the these dependencies for R_{qq} , R_{q1} and R_{11} coefficients obtained from kinetic theory and "perturbation cell" method for the range of temperatures $[325, \dots, 335]$ and for the range of chemical potential differences $[400, \dots, 1000]$.

FIG. 3: Dependence of R_{qq} on T and ψ obtained from kinetic theory for $\sigma_1 = 0.54$ and $\sigma_2 = 0.62$ (plane) and by "perturbation cell" method for $\alpha_{qq} = 9$, $\alpha_{1q} = 0$ and $\alpha_{11} = 3$ (points).

FIG. 4: Dependence of R_{q1} on T and ψ obtained from kinetic theory for $\sigma_1 = 0.54$ and $\sigma_2 = 0.62$ (plane) and by "perturbation cell" method for $\alpha_{qq} = 9$, $\alpha_{1q} = 0$ and $\alpha_{11} = 3$ (points).

The domain of T and ψ is not big, so the dependence on them is linear, as expected.

FIG. 5: Dependence of R_{11} on T and ψ obtained from kinetic theory for $\sigma_1 = 0.54$ and $\sigma_2 = 0.62$ (plane) and by "perturbation cell" method for $\alpha_{qq} = 9$, $\alpha_{1q} = 0$ and $\alpha_{11} = 3$ (points).

IX. DISCUSSION AND CONCLUSIONS.

In this paper we have studied stationary transport of heat and mass through the liquid-vapor interface in a mixture, using the square gradient theory [1, 2]. We derived an expression for the excess entropy production of a surface from the continuous description, which is identical to the one derived directly for the discrete description using the property of local equilibrium [3]. This makes it possible to give the linear force-flux relations for this case. These relations involve the interfacial resistivities or transfer coefficients, which were the main focus of interest in this paper. Given the numerical solutions of the non-equilibrium gradient model we were able to calculate these coefficients directly for a two-component mixture. This gives an independent way to determine the interfacial resistivities.

The main input parameters of the model, aside from the parameters in the equilibrium square gradient model, are the local resistivity profiles used to calculate the continuous solution. There is not much theoretical information about the numerical value of these resistivities. In the vapor phase one can use kinetic theory. In the liquid phase it is most appropriate to use experimental values. There is no experimental information about the local resistivities in the interfacial region. As the local resistivities change in the surface from one bulk value to the other, it is natural to assume that they contain a contribution similar to the profile of the order parameter. There is also evidence from molecular dynamics simulations for one-component systems [22] that there is a peak in the local resistivities in the surface. As we are in the framework of the gradient theory, it is naturally to assume that this peak is caused by a square gradient term, which is similar to the gradient contribution, which the Helmholtz energy density has in the interfacial region, namely $|\nabla\rho|^2$. The amplitude of this peak is not given by any theory and is used as a parameter. We therefore get that each of three local resistivities for a two-component mixture has the form given in Eq. (VI.6). Thus we get three adjustable amplitudes, α_{qq} , α_{1q} and α_{11} , two of which are found to contribute significantly to the value of the transfer coefficients.

In order to determine the typical values of the α 's we need to compare our results with independently obtained resistivities. Unfortunately, not much experimental data are available for multi-component resistivities and, to the best of our knowledge, no data are available for our system. Furthermore, no molecular dynamic simulations are available for mixtures. The only reasonable source of comparison is kinetic theory, which gives the expressions for the interfacial resistivities or transfer coefficients [15, 16]. We therefore compare our results to kinetic theory. Having three adjustable parameters in the gradient theory, α_{qq} , α_{1q} and α_{11} , and two adjustable parameters in kinetic theory, the condensation parameters σ_1 and σ_2 , we are able to match three diagonal coefficients R_{qq} , R_{11} and R_{22} . We found that R_{qq} does not really depend on α_{1q} and α_{11} . This makes it possible to fit α_{qq} using R_{qq} alone. For the values of the temperature and chemical potentials considered this gave $\alpha_{qq} \simeq 9$. We furthermore found that the interfacial resistivities did not really depend on α_{1q} . We therefore took this amplitude equal to zero. In kinetic theory R_{11} and R_{22} depend on the condensation coefficients σ_1 and σ_2 , respectively. Choosing $\alpha_{11} = 3$ gives values for the condensation coefficients of 0.54 and 0.62. As the components considered are very similar it is to be expected that

these coefficients are close to each other. The values of α 's obtained from the matching are such that the excess entropy production of the surface is positive, the second law is obeyed and the Onsager relations are valid. Having found the values of the α 's from the diagonal transfer coefficients the value of the cross coefficients follows uniquely.

We found that the values of the cross coefficients, obtained by our method are between 1-2 orders of magnitude larger than those found from kinetic theory. This confirms results from molecular dynamics simulations [12], where it was found that increasing the range of the attractive potential increased in particular the cross coefficients substantially above the values predicted by kinetic theory. This is an interesting result, indicating that kinetic theory underestimates the transfer coefficients for real fluids. This also indicates, that the effect of coupling will be important in the interfacial region. Experiments also confirm the importance of the cross coefficients [6, 7].

The effect of cross coefficients can be related to the measurable quantities, such as measurable heat of transfer $q_i^* \equiv -R_{qi}/R_{qq}$. This quantity can be associated both with gas and liquid phases in accordance to the corresponding heat fluxes. The difference $q_i^{*,g} - q_i^{*,\ell} = -(R_{qi}^g - R_{qi}^\ell)/R_{qq} = -(h_{i,eq}^g - h_{i,eq}^\ell)$ is equal to the difference of partial enthalpies between gas and liquid in equilibrium. This quantity is substantial, which indicates that $q_i^{*,g} - q_i^{*,\ell}$ is also substantial. This, in turn, makes the difference between the cross coefficients on gas and liquid side to be non-vanishing. This gives a theoretical ground for the importance of coupling in the interfacial region. Experiments [6, 7] confirm the size and importance of the heat of transfer on the gas side.

We did the comparison for one value of the temperature and chemical potential only. If one extends the analysis to a larger domain, one finds that the α 's depend on the temperature and the chemical potential difference; we refer to [17] in this context. The results of kinetic theory [13, 14, 15, 16] and molecular dynamics [11] both support the existence of a peak in the diagonal local resistivities and therefore the use of finite values for α_{qq} and α_{11} .

APPENDIX A: EXCESS IN CURVILINEAR COORDINATES.

1. On the definition of an excess quantity using curvilinear coordinates.

One may think of an alternative definition of an excess quantity

$$\hat{\phi}_a(x^s, x_2, x_3) \equiv \int_{x^{g,s}}^{x^{\ell,s}} dx_1 h_1 \phi^{ex}(\mathbf{r}; x^s) \quad (\text{A.1})$$

We note however, that $\hat{\phi}_a$ has no physical meaning, while $\hat{\phi}$ has. The reason for this is that

$$\Phi \equiv \iint_S dx_2 dx_3 h_2^s h_3^s \hat{\phi}(x^s, x_2, x_3) = \iint_S \int_{x^{g,s}}^{x^{\ell,s}} dx_1 dx_2 dx_3 h_1 h_2 h_3 \phi^{ex}(\mathbf{r}; x^s) \quad (\text{A.2})$$

is the total amount of some physical quantity in the volume which is limited by the surfaces S at $x^{g,s}$ and $x^{\ell,s}$, while

$$\Phi_a \equiv \iint_S dx_2 dx_3 h_2^s h_3^s \hat{\phi}_a(x^s, x_2, x_3) = \iint_S \int_{x^{g,s}}^{x^{\ell,s}} dx_1 dx_2 dx_3 h_1 h_2^s h_3^s \phi^{ex}(\mathbf{r}; x^s) \quad (\text{A.3})$$

is not. If the interfacial thickness is small compared to the radii of curvature, the difference between $\hat{\phi}$ and $\hat{\phi}_a$ is small and vanishes for planar interface considered under cartesian coordinates. However, it is Φ but not Φ_a which is a physical amount, and thus $\hat{\phi}$ is the surface density.

2. On the integration of a gradient function in curvilinear coordinates.

a. Consider a function ϕ being the divergence of a vector function: $\phi = \nabla \cdot \mathbf{q}(\mathbf{r})$. Then

$$\begin{aligned} (\nabla \cdot \mathbf{q})^{ex}(\mathbf{r}; x^s) &= \nabla \cdot \mathbf{q}(\mathbf{r}) - \{\nabla \cdot \mathbf{q}^g(\mathbf{r})\} \Theta(x^s - x_1) - \{\nabla \cdot \mathbf{q}^\ell(\mathbf{r})\} \Theta(x_1 - x^s) \\ &= \nabla \cdot (\mathbf{q}^{ex})(\mathbf{r}; x^s) + \mathbf{q}^g(\mathbf{r}) \cdot \nabla \Theta(x^s - x_1) + \mathbf{q}^\ell(\mathbf{r}) \cdot \nabla \Theta(x_1 - x^s) \end{aligned} \quad (\text{A.4})$$

where

$$\mathbf{q}^{ex}(\mathbf{r}; x^s) \equiv \mathbf{q}(\mathbf{r}) - \mathbf{q}^g(\mathbf{r}) \Theta(x^s - x_1) - \mathbf{q}^\ell(\mathbf{r}) \Theta(x_1 - x^s) \quad (\text{A.5})$$

and $\mathbf{q}^g$ and $\mathbf{q}^\ell$ are defined similarly to ϕ^g and ϕ^ℓ . Furthermore its excess

$$\widehat{\nabla \cdot \mathbf{q}}(x^s, \mathbf{r}_\parallel) = \frac{1}{h_2^s h_3^s} \int_{x^{g,s}}^{x^{\ell,s}} dx_1 h_1 h_2 h_3 (\nabla \cdot \mathbf{q})^{ex}(\mathbf{r}; x^s) \quad (\text{A.6})$$

Using the standard formula for the divergence of a vectorial function in curvilinear coordinates

$$\nabla \cdot \mathbf{q} = \frac{1}{h_1 h_2 h_3} \left(\frac{\partial}{\partial x_1} (h_2 h_3 q_1) + \frac{\partial}{\partial x_2} (h_1 h_3 q_2) + \frac{\partial}{\partial x_3} (h_1 h_2 q_3) \right) \quad (\text{A.7})$$

one can show that

$$\begin{aligned} & \int_{x^{g,s}}^{x^{\ell,s}} dx_1 h_1 h_2 h_3 \nabla \cdot (\mathbf{q}^{ex})(\mathbf{r}; x^s) = \\ & = h_2 h_3 q_\perp^{ex} \Big|_{x^{g,s}}^{x^{\ell,s}} + \int_{x^{g,s}}^{x^{\ell,s}} dx_1 \left(\frac{\partial}{\partial x_2} (h_1 h_3 q_2^{ex}) + \frac{\partial}{\partial x_3} (h_1 h_2 q_3^{ex}) \right) \end{aligned} \quad (\text{A.8})$$

Using the standard formula for the gradient of a scalar function in curvilinear coordinates

$$\nabla \theta = \frac{1}{h_1} \frac{\partial \theta}{\partial x_1} \mathbf{i}_1 + \frac{1}{h_2} \frac{\partial \theta}{\partial x_2} \mathbf{i}_2 + \frac{1}{h_3} \frac{\partial \theta}{\partial x_3} \mathbf{i}_3 \quad (\text{A.9})$$

one can show that for Heaviside step function Θ

$$\frac{1}{h_2^s h_3^s} \int_{x^{g,s}}^{x^{\ell,s}} dx_1 h_1 h_2 h_3 \mathbf{q}^b(\mathbf{r}) \cdot \nabla \Theta(x_1 - x^s) = \mathbf{q}^b(x^s, \mathbf{r}_\parallel) \cdot \mathbf{i}_1 \equiv q_\perp^b(x^s, \mathbf{r}_\parallel) \quad (\text{A.10})$$

Substituting Eq. (A.4) into Eq. (A.6) and using Eq. (A.8) and Eq. (A.10) we obtain

$$\widehat{\nabla \cdot \mathbf{q}}(x^s, \mathbf{r}_\parallel) = q_\perp^\ell(x^s, \mathbf{r}_\parallel) - q_\perp^g(x^s, \mathbf{r}_\parallel) + \widehat{\nabla_\parallel \cdot \mathbf{q}_\parallel}(x^s, \mathbf{r}_\parallel) \quad (\text{A.11})$$

where

$$\widehat{\nabla_\parallel \cdot \mathbf{q}_\parallel} = \frac{1}{h_2^s h_3^s} \int_{x^{g,s}}^{x^{\ell,s}} dx_1 \left(\frac{\partial}{\partial x_2} (h_1 h_3 q_2^{ex}) + \frac{\partial}{\partial x_3} (h_1 h_2 q_3^{ex}) \right) \quad (\text{A.12})$$

and we took into account that according to Eq. (III.1) $q_\perp^{ex}(x^{g,s}) = q_\perp^{ex}(x^{\ell,s}) = 0$.

b. Consider a special form of a vector $\mathbf{q}$ for which $\mathbf{q}_\parallel = \mathbf{J}_\parallel \phi$ where $\nabla_\parallel \cdot \mathbf{J}_\parallel = 0$. Here $\nabla_\parallel$ is a parallel component of three-dimensional nabla-operator so that

$$\begin{aligned} \nabla_\parallel \cdot \mathbf{q}_\parallel &= \frac{1}{h_1 h_2 h_3} \left(\frac{\partial}{\partial x_2} (h_1 h_3 q_2) + \frac{\partial}{\partial x_3} (h_1 h_2 q_3) \right) \\ \nabla_\parallel \theta &= \frac{1}{h_2} \frac{\partial \theta}{\partial x_2} \mathbf{i}_2 + \frac{1}{h_3} \frac{\partial \theta}{\partial x_3} \mathbf{i}_3 \end{aligned} \quad (\text{A.13})$$

Then

$$\frac{\partial}{\partial x_2} (h_1 h_3 q_2) + \frac{\partial}{\partial x_3} (h_1 h_2 q_3) = h_1 h_2 h_3 (\mathbf{J}_\parallel \cdot (\nabla_\parallel \phi) + (\nabla_\parallel \cdot \mathbf{J}_\parallel) \phi) = h_1 h_2 h_3 \mathbf{J}_\parallel \cdot (\nabla_\parallel \phi) \quad (\text{A.14})$$
